

Planning Guide / Product Range

Systems in Balance

Ventilating and Bleed Valve type 591
Ventilating Valve type 595

General

Optimal venting of your system

Ventilating and bleed valves regulate the exchange of air or gas in piping systems and allow your system to breathe easy

With ventilating and bleed valves, gas in tanks and piping systems can be removed, or alternatively they can be aerated to prevent a vacuum automatically and without the use of external energy.

The valves are designed differently depending on the specific venting requirements. GF Piping Systems offers valves for exhausting air which enters the pipes and tanks during filling and for admitting air during the emptying process.

ATTENTION!

A closed valve under operating pressure cannot vent!

Gases in the system

Ensure the safety and durability of your system thanks to controlled ventilating and bleeding – easily and economically.

Air accumulation in piping systems and vessels

Piping systems need to be free of air for optimal operating conditions. Air accumulation in the piping system can lead to dynamic pressure changes as a result of the different densities of the media and generally occurs at points in the pipeline with a lower operating pressure than in the surrounding sections.

Causes of air accumulation

During operation, dissolved air can be released by pumps, valves, fittings and other piping components, causing air to accumulate in the pipeline.

When filling vessels, tanks and pipelines or when servicing these, air can be admitted to the system. Also when dissolved air is outgassed from the medium during temperature and pressure fluctuations, excess air can be created in the system.

Effects of air accumulation

Air or gases in the system have significant negative effects on the entire installation.

- Flow reduction due to a restriction of the flow cross-section
- Pressure loss
- Dynamic pressure changes & water hammer
- Threat to the structural safety of the pipeline
- Distortion of flow volume measurements
- Damage to flow measurement devices
- Vibrations > damage to valves
- Dry running of pumps

Causes of negative pressure

Particularly at risk for a negative pressure forming in the piping system are the highest geodetic and hydraulic points in the pipeline. Discontinuities in the liquid column can create cavitation and mainly occur behind downstream from throttle points, line valves, pumps or turbines.

Switching off pumps, rapidly opening or closing valves or draining the pipeline (or just sections) can lead to water hammer and consequently also damages the pipeline, e.g. causing pipes to leak or burst. When operation of control and regulating valves is interrupted, negative pressure can also develop in the system.

Effects of negative pressure

Negative pressure or a vacuum can seriously damage a system.

- Damage to pipelines, tanks and medium-conveying components
- Increased incrustation due to suction effect
- Dislodged incrustation > valve blockage
- Break in the water column (incorrect measurement results, etc.)
- Pumps running dry

Function

Effective aeration and deaeration – a must

Protect your system

Functionality type 591

Deaerate when filling – aerate when emptying

The combination Ventilating and Bleed Valve type 591 from GF Piping Systems ensures complete and reliable aerating and deaerating of a tank or a pipeline and simultaneously serves as overflow protection. Depending on the filling speed, the float is lifted by the rising level of the liquid. At the same time, gases are removed from the system through the valve. When the pipeline or the storage tank is completely full, the float is pressed into the profile seal and closes the valve. The system is now completely deaerated. When the liquid sinks as a result of draining, the valve automatically opens again and air can flow in.

Valve open

Float rises when filling > deaerate

Functionality type 595

Aerate when draining

The Ventilating Valve type 595 was specially designed for the aerating process and is used wherever a safe and controlled air supply needs to be ensured. Gases/liquids are thus safely prevented from escaping to the environment (e.g. applications in the scope of the Federal Emissions Control Act / TA Luft 2 (technical regulations on air quality)).

The cone is pressed continually into the profile seal by the spring and only opens when there is negative pressure in the pipeline or the tank. The 595 valve allows the required volume of air to flow, thus equalizing the pressure and preventing negative pressure and the associated damages from occurring. Subsequently, the valve closes again by spring force.

Valve closed by spring force

Draining produces a negative pressure

Benefits of ventilating and bleed valves

The new ventilating and bleed valves feature a unique design – uniting innovation with efficiency.

The compelling features of GF Piping Systems Ventilating and Bleed Valves type 591 and 595 are the easy installation and compact design – focused on safety, ergonomics and operating efficiency.

The wide selection of materials, seals and dimensions allows using the valves in diverse types of environments and installing them in any desired system. Thanks to an innovative geometry, the valves from GF Piping Systems offer even more efficiency and precision and protect your systems in the following ways:

- Low investment costs
- Low total cost of ownership
- Long lifetime of valves
- Excellent chemical resistance – even with aggressive media
- Large variety of materials for numerous types of applications
- Customized configurations
- Large offering of suitable shut-off valves, special sets and piping components > one-stop shopping

Thanks to the comprehensive product range, the 591 and 595 valves are suitable for all conventional plastic piping systems – worldwide.

* ATTENTION!

Valve only vents automatically in unpressurized systems!

Valve closed and sealed tight

* Float sinks when draining > aerate

Valve opens, air flows in

Valve closes after pressure has been equalized

Installation

The right product, professionally installed

Safe operation with a professional installation

The instructions in the operating manual, operational safety and general safety regulations as well as the relevant norms and guidelines must always be observed.

The valves may only be operated in the indicated pressure and temperature range:

- The ventilating and bleed valve must always be built in vertically
- The right dimensioning is a prerequisite
- The valves are installed at the highest point of the system – where gases accumulate
- Fill slowly, because filling too fast can cause liquids to leak through the ventilating and bleed valve
- The valve should be easily accessible for operating, functionality checks and maintenance work

Installation in pipelines

If the system is filled too rapidly, the medium could spill over due to the cone's inertia.

We therefore recommend always installing a shut-off valve (e.g. BV 546) upstream of the ventilating and bleed valve. By opening the valve slowly, the venting speed can be controlled manually and overflow prevented.

Also, with a closed ball valve, installing and removing the valve or function testing is always possible without having to shut down operation.

In addition to a shut-off valve, an adequately dimensioned ventilation dome is important for correct valve installation. If not specified in detail, it should correspond in height to the diameter of the pipeline. The nominal diameter of the dome should be approximately half of the pipe cross-section.

Tender specifications

Ventilating and bleed valves

Ventilating and bleed valves should be available in the dimensions DN10-100 and have a pressure rating of PN10/PN16. They should be equipped with a PP-H float having a density of 0.91g/cm^3 .

All ventilating valves should be available in the dimensions DN10-100 and have a pressure rating of PN16. They should be equipped with a plastic-coated stainless steel spring and should have a minimum opening pressure of 10-80 mbar.

Example

Pipeline: d50
 Height of ventilation dome: ca. 50 mm
 Nominal diameter ventilation dome: d25

Product details

Material of valve body	PVC-U, PVC-C, ABS, PP-H, PVDF
Dimensions	d16DN10 - d110DN100, $\frac{3}{8}$ " - 4"
Pressure ratings	PVC-U, PVC-C, PVDF: PN 16 PP-H, ABS: PN10
Connections	Solvent cement sockets ISO, BS, ASTM/ANSI, JIS Solvent cement spigots ISO Threaded sockets
Sealing materials	EPDM, FPM, FFPM
Float materials	PP-H, PVDF
Spring material for type 595	Standard: V2A, Nimonic Optional: V2A Halar coated
Approvals	ACS, DIBt, FDA TA-Luft, NAMSA

Spare parts

Elements, such as the central part, can be reordered for the ventilating and bleeding valves at any time.

Installation

Installation Tank ventilation

Venting and bleeding – pollutant-free media

If the medium in a tank is not considered a pollutant according to TA Luft regulations, a simple venting and bleed connector is sufficient.

Through an opening on the top side, the tank can be conventionally aerated and deaerated via the atmosphere. In pollutant-free applications, a ventilating and bleed valve is not absolutely necessary.

Venting and bleeding – at the highest point

Here too, the aforementioned safety characteristics and installation conditions apply. Depending on their toxicity, excess gases can be conducted directly into the atmosphere or washed in a scrubber. Other gases in the system are bled off at the highest point.

Venting and bleeding – hazardous media

If a medium is rated as a pollutant according to technical regulations for air quality (TA Luft), the vapours from the system must be discharged in a controlled manner. Gases and vapours from pressure release valves must be – provided there are no safety-related objections – conducted to the gas collection system or a waste gas purification facility. A popular method is cleaning via a scrubber or an absorption cylinder.

When filling the storage tank with compressed air, care should be taken that the compressed air does not expand suddenly in the fill line. This can damage pipes, valves and storage tanks.

In the absorption cylinder, it is important to ensure that the

water column is not higher than the permissible negative pressure in the tank. As no vapours are allowed to escape, the valve only takes over the task of ventilating. The 591 and 595 valves are ideal for this, depending on the installation. It should be ensured that the tip of the cone always points down (toward the ground); the valve must be able to open under negative pressure.

When using type 595, it has to be ensured that the opening pressure of the valve is less than the permitted negative pressure of the vessel.

Frost in winter or medium condensate can cause the cone to stick. Before starting, check that the cone sits loosely in the housing and can move freely (tapered rod). The system must be kept completely frost-free.

Calculation basis for the right valve

Dimensioning

The working pressure range should be defined so that the maximum operating pressure lies within this range, otherwise the valve will not open. The appropriate type and size of ventilating and bleed valve should be selected so that the respective air volume can be conducted off under working pressure.

Opening conditions type 595

DN (mm)	10	15	20	25	32	40	50	65	80	100
Required vacuum to lift the cone (bar)	0.028	0.028	0.030	0.030	0.035	0.040	0.050	0.060	0.060	0.060

Density of the medium

To ensure that the cone has optimal lift, the specific weights of the cone materials should be noted in relation to the density of the medium.

Cone material

Cone material	Density
PP-H	0.91 g/cm ³
ABS	1.03 g/cm ³
PP-TV (talc)	1.05 g/cm ³
PVC-U	1.38 g/cm ³
PVC-C	1.50 g/cm ³
PVDF	1.78 g/cm ³

Calculations for valve configuration

To select the correct valve size, the max. flow (Q in m³/h) is first calculated.

To do this, the flow velocity of the medium (vr) is required, as is the inner diameter of the medium-conveying pipe (di).

$$Q = V_r * \frac{\pi}{4} * d_i^2 * 0.001 * 3.6$$

The volume flow of the medium can be equated with the gas volume to be discharged or filled.

If several aerating or deaerating valves are used, each valve must be configured for the maximum flow velocity. With the calculated volume flow, the correct valve dimension can be determined from the air volume diagram. The velocity in this diagram corresponds to the discharge velocity of the gases at the valve. It is recommended that, if possible, 20m/s is not exceeded to prevent excessive wear on the valve.

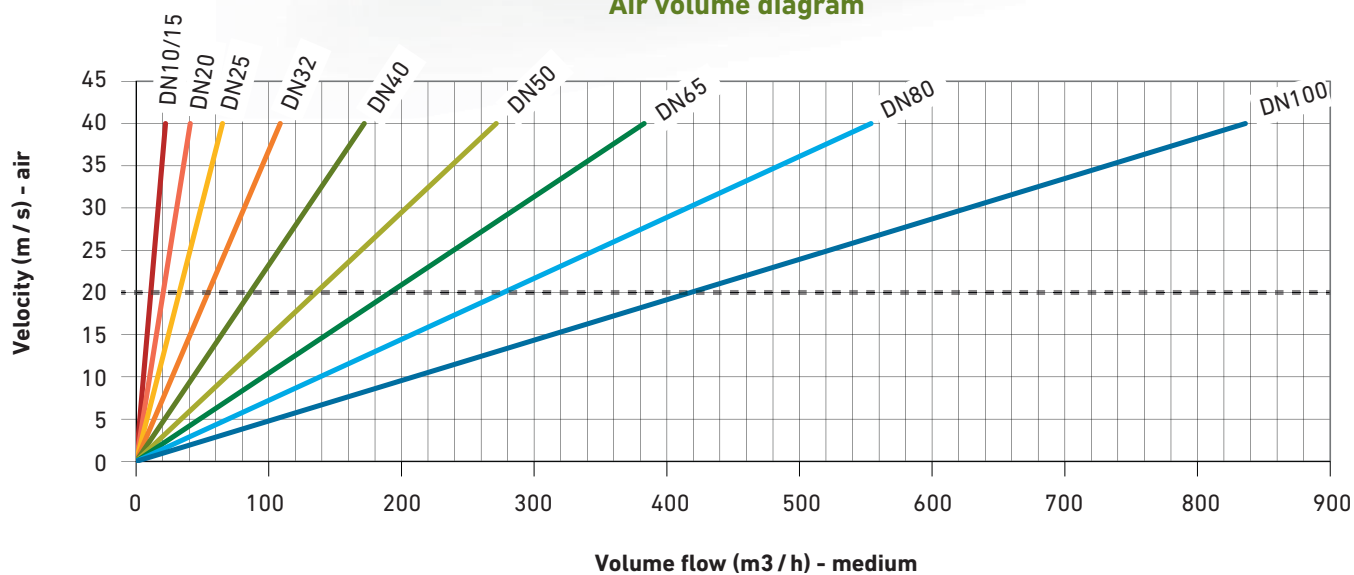

Air volume diagram

For smooth operation and a long service life, bleeders should not be overdimensioned. If the flow rate is too high for the predetermined nominal diameter of the connector, the problem can be remedied by increasing the working pressure range with correspondingly lower flow rate.

For more information, please see the Georg Fischer Planning Fundamentals, which serves as a detailed reference work in selecting a valve, or consult our website.

Air volume diagram

--- A speed of more than 20 m/s is not recommended. We suggest about 10 to 15 m/s as optimal speed range.

Ventilating valve type 595 PVC-U With solvent cement spigots metric

Model:

- With protection cap up to DN50 made of PP-GF, DN65-100 made of POM
- Spring loaded, spring made of NIMONIC 90, HALAR coated
- Spring available in other materials, see spare parts
- Designed for easy installation and removal
- Compact installation length
